A: The docker image has not been built for that platform. The image is built for Windows or Linux and should work on OS X or other Unix-like systems. To build the image you can use a "convention over configuration" approach. The makefile creates all the necessary things for the build, such as a dockerfile,.spec file and docker-compose.yml to run the container. So to build the image you just need to run `$ make docker` Then you can run the image locally like so: `$ docker run -it docker:1.10.0-rc7 /bin/bash` It is also possible to use Docker to "dock" a container inside your system. If you take a look at the Docker website, they provide step-by-step instructions on how to do that using the Docker Desktop application. You can also take a look at the Docker Hub page to see what images are available. Q: Can I store all information about image files on a website with only the user's credentials (hashed password) available? I have a website, and all I need is to be able to retrieve image files stored on it. The site is mostly used by a small group of people, so I'd like to keep the website

relatively small (and expandable), as it's just a hobby, but I also don't want to sacrifice security. I want to make sure the security is at least at the level of a web directory that just stores files. Does anybody know whether this is secure enough? I've done some reading on the subject, and I was thinking about storing the user's credentials (the hashed password) in the PHP file, and setting the permissions to 755 for the directory I'm storing the files in. I'm not sure how the permissions for images work (specifically on how to place the images in it?), but I'd like to make sure it's safe. Also, does anyone have any security recommendations for this kind of setup? I'm not a security expert by any means, just looking for some educated opinions. A: You probably will be storing user information in the file directory somewhere, and as an admin, you may decide to add certain directives in the .htaccess file. As long as the files are served by Apache, making use of an htaccess file, everything should be fine - with d0c515b9f4

Ubuntu 14.04 LTS (14.04) release. Beaglebone Black (BBB) board. The Raspberry Pi computer, a board based on a single-board computer (SBC) from the UK company Raspberry Pi. The Raspberry Pi computer is a single-board computer developed by the Raspberry Pi Foundation. The Raspberry Pi computer is a low-cost single-board microcomputer designed to encourage people to learn computer programming. The main ARM Cortex-A8 processor is an MIPS R4000 variant with 1 GB of RAM, a 16 MB QVGA-resolution touchscreen display, two USB ports, a 40-pin GPIO header, and a composite video output. The board runs the Linux operating system, and the Linux kernel was chosen because most of the major open source operating systems are available for it: Android, Chrome OS, Firefox OS, SailfishOS, Windows RT, and Windows 8 have all been ported. In addition to the GUI, the Linux kernel supports the console and serial output ports. The base model of the Raspberry Pi is the Raspberry Pi Model A, followed by the Model B, Model A+ and Model B+, Model A2, Model B2, Model B2+, Model A3, Model A+3 and Model B+3. The newer variants have a faster CPU, more RAM, updated GPU, a USB hub and are named Model A, A+ and B. A mini card reader and SD card are also available, for expanding the storage.Q: Is it possible to get the path to a database without using libpq? In PostgreSQL or MySQL, one can do: `SELECT dbname FROM information_schema.schemata WHERE schemaname = 'dbname'`; Is there a way to do this without using libpq? I am interested in a vendor-agnostic solution.
