What happens is that it stores the 32bit result and I want to store the 64 bit result. I found this question from a previous interview. The interviewer hinted that the operands must be converted (from 32 bit to 64 bit). I couldn't find the answer anywhere online. Is this the way to go about it? A: Your basic principle, for using 64-bit floating point values, is similar to other X87 and SSE instructions. You use 3 operands: the two source operands and the destination, which is an XMM register or memory location. So, the inputs would be considered to be: xmm2 the source, xmm3 the source, and rsp the destination. To convert the source numbers to the destination, you use several floating-point instructions, starting with fld to load the source values into the destination and ending with fstp to store the result. (And, in your case, you also need to negate the destination.) Not all of
